

Fortification of organic manures with iron on nutrient release characteristics

ABSTRACT

Aims: The objective of current study was to examine the nutrient release pattern by enriching iron fertilizer with different organic manures at different ratios in regular sampling intervals.

Study design: The design used in this current study was Factorial completely randomized block design with six treatments replicated thrice.

Place and Duration of Study: An incubation experiment was carried out in the Department of Soil Science and Agricultural Chemistry, Tamil Nadu Agricultural University, India during December - March 2022.

Methodology: An incubation experiment was carried out by enriching inorganic iron fertilizer with three different organics such as FYM, vermicompost and biocompost in two ratios viz., 1:5 and 1:10 at four different sampling intervals 7, 14, 21 and 28 days after incubation and analyzed for various physical and chemical properties to study the iron release pattern.

Results: The results revealed that the iron content ranged from 5324 to 8823 mg kg⁻¹. among all the combinations, the highest nutrient release was found in FeSO₄ enriched with vermicompost 1:10 ratio at 21 DAI which is followed by FeSO₄ enriched with FYM 1:10 ratio.

Conclusion: The present study revealed that the integrated application of organic and inorganic fertilizer significantly improved the efficiency of chemical fertilizers. Only a few work were reported on integrated application of micronutrient at different organic fertilizer rates, however need further studies to validate the reliableness.

Keywords: Iron fertilizer; organic manures; enrichment; iron use efficiency.

1. INTRODUCTION

Micronutrient deficiency in plants is an alarmingly increasing global issue. Among the micronutrients, iron (Fe) is a crucial element for plants due to its role in photosynthetic activity which determines the yield of crop. The total iron content in the earth crust though is high, it doesn't reflect on supplying capacity of soil and nutrient available pool to plants. Generally, Fe chlorosis occurs as result of poor availability of Fe for crops [1]. Although Fe is the fourth most abundant nutrient in the earth's crust, it is the third-most scarce element for growth of the plant mainly by the nature of low solubility [2]. Iron plays an indispensable role in numerous pathways in plant system. It serves as a constituent of several enzymes and

requisite for copious biological actions. It is also involved in chlorophyll synthesis, and prerequisite for chloroplast structure and its function maintenance [3].

Favorable effects of organic manures were already known in ancient era but the potential of enriching organic manures with inorganic fertilizers has been recognized recently. Chemical fertilization has flourished good results in certain circumstances, and adverse effects have been reduced by using combined application of organic and inorganic fertilizers [5]. Organic manures solitarily do not contribute remarkable surge in crop yields owing to the low nutrient reserves. Consequently, to sustain soil productivity, combined use of inorganic and organic manures needs to be implemented. Continuous applications of organics aggravate to proliferate the beneficial microbes and strengthening the physical characteristics of the soil. However, chemical fertilizers provide certain nutrients and the soil cannot contribute in sufficient amounts. Accordingly, judicious blending of organic manures and inorganic fertilizers support to sustain soil health and its productivity. [5], [6] reported that combination of cow dung and inorganic fertilizer found to improve the efficiency of chemical fertilizers significantly.

Organic sources have ability to complex Fe and increase its solubility and mobility [7]. Organic amendments contain organic compounds which are highly capable of chelating Fe. These chelators of Fe in organic sources are mostly humic acids, amino acids, phenolics, hydroxamates and catechol siderophores [8]. Organic sources not only help in increasing Fe solubility by providing chelators but also stimulate the microbial activities which results in powerful siderophore production [9], [10]. Although FeSO_4 is extensively applied fertilizers for nature of quick solubility, affordability in the market, nutrient fixation is the crucial issue in soil. Under such circumstances augmented methods like synthetic chelates usage can be approved to aggravate the insubstantial utilization of micronutrients. Besides using synthetic chelates like Fe-EDTA, EDDHA-Fe which is costly, making use of organic manures that act as natural chelates for enrichment sounds to be economically viable. Many iron fertilizers are available for controlling of iron chlorosis, but their high costs generally restrict wide use of iron sources in agriculture. And hence, by using combined application of manures and inorganic fertilizers paves the way for higher nutrient release. There are few studies were reported on integrated application of micronutrient at different organic fertilizer rates. Hence, a laboratory incubation experiment was carried out with an objective to study the nutrient release pattern with the addition of fortified organic manure with inorganic iron fertilizer viz., FeSO_4 .

2. MATERIAL AND METHODS

An incubation experiment was carried out in the Department of Soil Science and Agricultural Chemistry, Tamil Nadu Agricultural University, Coimbatore, India during Dec 2021-March 2022, to study the nutrient release pattern of organic manure fortified with inorganic iron fertilizer. Three types of organics, viz., FYM, Vermicompost and biocompost were collected from the farm at the Tamil Nadu Agricultural University and used for the study. Different sources of organics were air dried, powdered to pass 2-mm mesh and mixed thoroughly and were enriched with inorganic iron fertilizer (Ferrous sulphate - $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$) @ two different ratios. The enrichment treatments consisted of 1:5 and 1:10 ratio of ferrous sulphate with three different organics i.e., FYM, vermicompost and biocompost studied at four different incubation intervals such as 7, 14, 21 and 28 days. The mixture was turned over periodically (weekly) and moisture level was maintained till the completion of the study. The enrichment study was conducted as per the treatment schedule, water was added to maintain 65% moisture holding capacity and sampling was done periodically at 7, 14, 21 and 28 days of incubation. The enriched samples were air dried, powdered and sieved through 2 mm sieve

and analyzed for various physical properties and chemical properties by adopting standard procedures.

2.1 Physical properties of enriched samples

The physical properties like pH, EC, bulk density, particle density and porosity were analyzed. The enrichment samples were analyzed for pH and EC in 1:5 ratio manure - water suspension [11]. The bulk density, particle density and porosity of the enriched samples were analyzed by cylindrical method [12].

2.2 Chemical properties of enriched samples

Chemical properties like DTPA extractable micronutrient Fe was analyzed in Atomic Absorption Spectrophotometer as per the procedure of [13].

2.3 FTIR

FTIR is a promising technique for identification of functional groups in the fortified organic manures. Use of instrumental technique like FTIR analysis reveals the featured changes in the characteristics of functional groups during the process of enrichment.

2.4 Statistical Analysis

The data obtained from experiment were subjected to statistical analysis using AGRESS software version 7.01. The level of significance used was $P < 0.05$. Critical difference (CD) values were calculated for the $P < 0.05$ whenever "F" test was found significant [14].

3. RESULTS AND DISCUSSION

Organic manure fortified with inorganic iron fertilizer significantly influenced the pH and EC of the enriched manure. The results showed that pH during the incubation ranged from 5.09 to 5.7, 4.94 to 5.65, 4.88 to 5.47 and 4.77 to 5.38 respectively on 7th day, 14th day, 21st day and 28th DAI. Among the different treatments, minimum pH reduction of 5.11 was observed in the manure FYM @ 1:5 ratio, and maximum pH reduction of 5.47 was observed in vermicompost @ ratio of 1:10. The pH of the enriched manure showed a declining trend with incubation period in all treatments irrespective of the manures. Among all the treatments, T₄ - FeSO₄ enriched with vermicompost at 1:10 ratio accounted for a higher reduction in pH with the value of 5.47 at 21 DAI. [15] reported that soil pH gradually decreased with increasing incubation time. In the proposed incubation experiment, the influence of enriched organic manure with micronutrients decreases the EC and it was clearly demonstrated. Changes in EC during the incubation ranged from 3.76 to 6.52 dS m⁻¹, 3.69 to 6.36 dS m⁻¹, 3.56 to 6.14 dS m⁻¹ and 3.48 to 5.85 dS m⁻¹ on 7th day, 14th day, 21st day and 28th day respectively. Minimum EC reduction of 5.38 dS m⁻¹ was noticed in the vermicompost @ ratio of 1:10, and maximum EC reduction (5.46 dS m⁻¹) in vermicompost @ ratio of 1:10. As the incubation period progressed from 7 to 28 days, the electrical conductivity began to decline. Among all the treatments, higher reduction in EC was observed in treatment T₄, with the value of 5.46 dS m⁻¹ at 21 DAI. Vermicompost or worm manure is rich in plant growth regulators and enhances more microbial load [16]. Microbial activity is more because of the increased and exposed surface area that favors the decomposition much faster [17], [18]. Additionally, earthworms ingest huge quantity of organic materials rich in nitrogen and enhances N mineralization [19]. This might be the reason for reduction in pH and EC. This finding supports [20]'s earlier findings. The drop in EC could be related to the production of organic acid during the decomposition of inorganic iron fertilizer-enriched manures. Organic

matter induced leaching of excessive ions by enhancing the physical property of soil, which also results in lower EC. [21].

3.2 Bulk density, particle density and porosity

Fortification of organic manure with inorganic fertilizer also plays a vital role in influencing bulk density, particle density and porosity of the enriched products. The bulk density of the Fe-enriched manure showed a declining trend and particle density and porosity showed an increasing trend over incubation period. The results revealed that changes in bulk density during the incubation ranged from 1.10 to 1.21 g/cm³, 1.08 to 1.20 g/cm³, 1.06 to 1.19 g/cm³ and 1.05 to 1.18 g/cm³ respectively during 7th day, 14th day, 21st day and 28th day after incubation. Minimum bulk density reduction of 1.18 g/cm³ was recorded in the biocompost @ ratio of 1:10, and maximum bulk density reduction (1.13 g/cm³) was noticed in vermicompost @ ratio of 1:10. Among the various treatments, T₄ -FeSO₄ enriched with vermicompost @1:10 ratio accounted for a higher reduction in bulk density (1.13 g/cm³) at 21 DAI. With regard to particle density during the incubation, it ranged from 2.54 to 2.80 g/cm³, 2.56 to 2.85 g/cm³, 2.57 to 2.92 g/cm³ and 2.59 to 2.97 g/cm³ respectively during 7th day, 14th day, 21st day and 28th day of incubation. Minimum particle density increment (2.57 g/cm³) was registered in the vermicompost @ ratio of 1:5, and maximum particle density increment (2.92 g/cm³) was observed in vermicompost @ ratio of 1:10. Similar results were recorded with respect to porosity also and, during the incubation it ranged from 52.8 to 58.2 %, 53.9 to 59.3%, 55.2 to 61.3 % and 55.2 to 62.3 % at 7th day, 14th day, 21st day and 28th day of incubation respectively. Minimum porosity raise of 54.5 % was observed in the FYM @ ratio of 1:10, and maximum porosity raise (61.3 %) was recorded in vermicompost @ ratio of 1:10. The particle density and porosity were found to be high in T₄ -FeSO₄ enriched with vermicompost 1:10 ratio having value of 2.92 g/cm³ and 61.3 % respectively at 21 DAI. Due to organic manures decomposition that increases microbial load and the spaces between particles and thus increases the void ratio. The results are in accordance with those of [22], who found that using organic manure in combination with chemical fertilizer reduced soil bulk density, increased particle density, and increased total porosity.

Table 2 Effect of Fe-fortified organic manure on the bulk density, particle density and porosity

3.3 Iron content

The use of fortified organic manure with inorganic iron fertilizer greatly increased the availability of DTPA extractable iron in the current investigation. The DTPA - Fe showed an increasing trend of availability from 7 DAI to 21 DAI and thereafter declined at 28 DAI. Changes in iron content during the incubation ranged from 5324 to 6968 mg kg⁻¹, 6744 to 8531 mg kg⁻¹, 7084 to 8823 mg kg⁻¹ and 6917 to 8609 mg kg⁻¹ respectively at 7th day, 14th day, 21st day and 28th day of incubation. Minimum iron content of 5324 mg kg⁻¹ was observed in the biocompost @ ratio of 1:5, and maximum iron content of 8823 mg kg⁻¹ was recorded in vermicompost @ ratio of 1:10.

Though, all the levels of iron enrichment were efficient in increasing the iron availability, among the different manures, T₄- enrichment of FeSO₄ with vermicompost 1:10 ratio accounted for the high Fe availability. It was found to be high at 21 DAI with DTPA- Fe content of 8823 mg kg⁻¹ which was followed by T₂- enrichment of FeSO₄ with FYM 1:10 ratio with the value of 8274 mg kg⁻¹. It is well known that the availability of micronutrients in soil is

Tr	Bulk density (g/cm ³)				Mean	Particle density (g/cm ³)				Mean	Porosity (%)				Mean

mostly determined by soil pH and organic matter level. The increased iron availability might be due to the role of humic substances in the manure which increased micronutrients availability by preventing their transformation as insoluble hydroxides, chelation action and releasing them in labile forms [23]. A similar finding was also reported in soil by [24] and they found significant influence of Fe-fortified vermicompost on availability of iron due the complexation or chelation action, contribution from manures and prevention from fixation of iron.

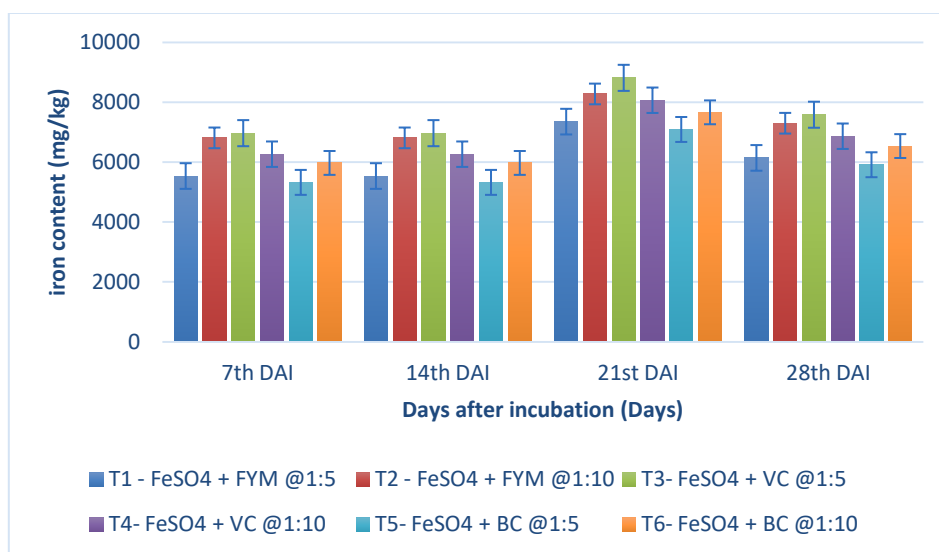

Fig.1. Effect of fortified organic manure on the DTPA- Fe content

3.4 FT-IR

The infrared spectroscopy of raw manure sources and the best result of the enriched manure was characterized by main absorbance bands at 1739 cm^{-1} (C=O stretch), 1228 and 1216 cm^{-1} (C–O stretch & O–H stretch), 1367 cm^{-1} (C–O stretch), 2970 and 2946 cm^{-1} (C–H stretch), 3016 cm^{-1} (NH_2 stretch), 1438 cm^{-1} (COO– stretch) and 3456 cm^{-1} (C–H stretch). The presence of aliphatic C–H stretching, stretching vibration of –OH and CO– bonds, and COO– stretching were highly remarkable in the enriched samples and this indicates the mineralization of nutrients through the enrichment process. The highest peak intensity was observed in the best enrichment manure i.e., inorganic fertilizer (ferrous sulphate) enriched with vermicompost at the ratio of 1:10. As compared to all other raw manure sources, the high intense peak was observed in the region of 1739 cm^{-1} , vibration of C=O stretch which is the functional groups of carboxylic acids, aldehyde and ketone [25].

Table 3. Assigned values for different peaks in FTIR

Wavenumber cm^{-1}	Vibration	Functional groups
3456	O–H stretch	Phenols and carboxylic groups
3016	NH_2 stretch	Primary amides
2946	C–H stretch	Aliphatic methylene groups of lipids and fats
1739	C=O stretch	Aldehyde, ketone, carboxylic acids and esters
1438	COO– stretch C–N stretch	Carboxylic acids Amide III
1216	C–O stretch	Alcohols, ethers and esters

Source: [26]

The highest nutrient release in the enriched manure might be due to the functional group of carboxylic acids released from the decomposition process. The acid chelates and increases the available form to labile and the similar findings were also in accordance with the results of [27].

4. CONCLUSION

Organic manures increase soil fertility and crop production potential possibly by changes in soils physical and chemical properties including nutrient bioavailability, water holding capacity, soil pH, microbial community and activity etc. Furthermore, our finding showed that integrated application of organic and micronutrients fertilizer significantly improved the

efficiency of chemical fertilizers. The results both physical properties like pH, EC, bulk density, particle density and porosity and chemical properties like DTPA – Fe content of the laboratory incubation experiment showed significantly better results for treatment FeSO₄ enriched with vermicompost 1:10 ratio in reducing the pH and EC and increasing the micronutrient availability which was comparable with the results of enrichment of FeSO₄ with FYM 1:10 ratio.
