

Awareness of diabetic foot and its risk factors in the general population of Arar, Northern Saudi Arabia

Abstract:

Background: Foot ulcers may be complicated to toe amputation or limb amputation which can be prevented by patient education on self-management and appropriate foot care procedures. **Study objectives:** The objective of this study is to determine the awareness of diabetic foot and its risk factors among the general population of Arar city, Northern Saudi Arabia. **Methods:** An analytical cross-sectional study was carried out in primary health care centers in Arar, Northern Saudi Arabia, during the period from 1st September to 10th October 2021. Data was collected by personal interview with the attendees of the primary health care center, using a predesigned questionnaire. **Results:** Almost 60% of participants have knowledge about diabetic foot. Source of information about diabetic foot was doctors and nurses in 13% and 11.9% social media in our study population. 62.7% think that diabetic foot risk may be reduced by controlling blood sugar level, 13% by checking the feet every day and several times a day, and 9.2% reported wearing shoes and socks on a daily basis. 65.6%, 66.7%, 48.4%, 82.6% and 62.1% knew that skin infections, foot abscess, bone infections, gangrene, and foot deformity are complications of diabetic foot respectively. Good knowledge of diabetic foot was significantly associated with age and educational level but not with marital status. **Conclusion:** The level of knowledge of diabetic foot and its related complications is relatively low. Due to the high incidence of diabetes mellitus (DM) in Saudi Arabia, it is vital that the population has appropriate information and awareness about this illness to enable continued promotion of public health measures to limit its prevalence. It is also crucial for DM patients to understand the medication and lifestyle modifications that may enable them to better regulate their blood glucose and prevent the complications.

Key words: knowledge, diabetic foot, diabetes mellitus, complications, Saudi Arabia, awareness, lifestyle modifications.

Introduction:

Diabetes mellitus (DM) is known to be one of the most challenging problems in public health. Recent research in Saudi Arabia showed that more than 44% of people aged 55 or older had severe uncontrolled diabetes with long-term complications [1]. It is expected that the diabetes prevalence will increase to reach 333 million by the year 2025, with the highest prevalence occurring in developing countries [2]. The prevalence of diabetes differs between countries in Eastern Mediterranean Region (EMR). Rank of Saudi Arabia is the second-highest country with regard to the prevalence of diabetes mellitus (DM) in the Middle East and seventh in the world. The prevalence of diabetes in Saudi Arabia was reported as 13.4% in Saudis aged 15 years or older [3]. Diabetic foot complications are considered the most common diabetes complications with 4 to 10% prevalence in the diabetic population [4]. These diabetic complications are an increasing public health problem and constitute a leading cause of admission, amputation, and mortality in diabetic patients. Diabetic People are prone to get foot ulcers, amputations, and other lower limb clinical abnormalities if they do not have good knowledge about foot care practice [5]. Foot ulceration is one of the most common complications of diabetes [6]. Of diabetic people, 20% are at high risk of foot ulceration due to neuropathy [7]. In Saudi Arabia, there are several conducted studies showing the varying prevalence of diabetic foot ulcers from 26.0% to 61.8% [8]. The main factors that lead to the development of diabetic foot abnormalities are mechanical stress, neuropathy, and angiopathy. Sensory neuropathy results in a reduction of sensation making the foot more prone to trauma eventually leading to skin breakdown and foot ulcer formation [9]. Foot ulcers can cause severe disability and hospitalization to patients and a considerable economic burden to families and health systems [10]. Infection is a further complication that occurs in about half of diabetic foot ulcers. About 85% of diabetes-related amputations are preceded by foot ulcers, and it accounts for more than half of non-traumatic lower-limb amputations [11]. Foot complications increase the risk for amputation in diabetics by 12.3 folds as compared to the non-diabetic population [12]. More than 50% of lower limb amputations are performed on diabetic patients, around 3970 in KSA [13]. One of the most important ways to manage diabetic foot ulcers is the proper care and prevention of injuries to the foot. This requires patients and their caregivers to have proper education, awareness of proper care, and knowledge about the management of foot ulcers. [14].

Study objectives:

The objective of this study is to determine the awareness of diabetic foot and its risk factors among the general population of Arar city, Northern Saudi Arabia.

Methods & participants:**Study design, setting and period:**

A cross sectional community based study was carried out in primary health care centers in Arar, Northern Saudi Arabia, during the period from September 1st to October 10th 2021.

Inclusion criteria: age between 18 and 75 years, both genders and all educational levels.

Exclusion criteria: Older than 75 or younger than 18 years and Non Saudi residents.

Sample Size:

The included sample was calculated using the following formula:

$$N = Z^2 \times P(1-P) / E^2$$

Where:

N = sample size

$Z^2 = 1.96$ (The critical value that divides the central 95% of the Z distribution from the 5% in the tail)

P= the prevalence, of awareness regarding diabetic footand its risk factors among the general population of Arar.

E2 = the margin of error (= width of confidence interval)

So, by calculation, the sample size is equal to 384 cases with 10% as drop-out rate, so total sample size must be more than 415 individual.

Sampling Technique:

The participants was selected using the systematic random sampling technique. Data was collected from all adult Saudi male and female attendees of 5 randomly selected primary health care centers (PHC) in Arar city. We included all the population attending the PHC centers for any cause, not only the patients. After identifying the first participant randomly, then every 3rd attendant was interviewed to be included in the study till the required sample is covered. Data was collected through personal interviews with the selected population and filled the questionnaire which guided us to the required data according to the study objectives.

Data collection tool:

A predesigned questionnaire was used for data collection. It is composed of two sections. Section 1 includes socio-demographic characteristics of the

participants (age, gender, marital status, educational level and occupation). The second section assessed the knowledge and awareness of the population about the diabetic foot and its risk factors. A written informed consent was obtained from all participants before the interview.

Ethical considerations:

The research proposal was approved by the Regional Research and Ethics committee in Northern Border University, KSA(HAP-09-A-043), with letter number (3/43/H). Data collectors gave a brief introduction to the participants by explaining the aims and benefits of the study. Informed written consent was obtained from all participants. Anonymity and confidentiality of data was maintained throughout the study.

Data management and Statistical analysis:

The collected data was entered and analyzed using the Statistical Package for the Social Science (SPSS Inc. Chicago, IL, USA) version 23. Descriptive statistics was performed. Percentages was given for qualitative variables. The determinant factors were determined using the Chi-square test. P-value was considered significant if $P < 0.05$.

Results:

Table (1) shows the sociodemographic characteristics of participants. According to the table 39.8% of studied sample aged between 20- 30 years and 24.7% aged between 41- 50 years. 68.3% of sampled participants were married and 28.5% were single. 58.5% were females. 92.2% of participants were highly educated (university or more) almost 60% of participants have knowledge about diabetic foot.

Table (2) illustrates the knowledge of participants about symptoms and source of information about diabetic foot. In the table; the source of information about diabetic foot was doctors and nurses in 13% and 11.9% social media in our participants. 62.7% reported that diabetic foot risk may be reduced by controlling blood sugar level, 13% by check the feet every day and several times, and 9.2% reported wearing shoes and socks on a daily basis.

Table (3) shows the knowledge of diabetic foot variables among the participants. The data showed that 65.6%, 66.7%, 48.4%, 82.6% and 62.1% knew that skin infections, foot abscess, bone infections, gangrene, and foot deformity are complications of diabetic foot respectively.

Table (4) presents the association between good knowledge about diabetic foot and sociodemographic variables. Good knowledge about diabetic foot was significantly associated with age and educational level but not with marital status

Table (1): Sociodemographic characteristics of participants (n=1046).

Parameter		No.	Percent
Age (years)	• Less than 20	78	7.5
	• 20-30	416	39.8
	• 31-40	202	19.3
	• 41-50	258	24.7
	• 51-60	88	8.4
	• More than 60	4	.4

	University or more	568	396	964	
		94.0%	89.6%	92.2%	

Discussion:

According to the International Diabetes Federation, Saudi Arabia has the highest rate of DM in the MENA region (prevalence rate of 17.7%). Saudi Arabia has the fourth highest incidence of T1DM in the world, at about 33.5/100,000 persons per year. A registry-based data of Saudi estimated foot complications among 3.3% of diabetic patients with majority having foot ulcer. The foot ulcer is often succeeded by complications and deterioration of quality of life [15]. In addition, lower extremity amputation is associated with prolonged hospitalization and rehabilitation and also require home care and social support. Overall, the rate of lower limb amputation in diabetic patients is 10–30 times higher than non diabetics. The studies showed that every 30 seconds one leg is amputated due to diabetes in the world. In the first two years after amputation, there is a 50 percent risk of re-amputation and three years after lower limb amputation, 50% of patients may be dead.

According to our results; almost 60% of participants have knowledge about diabetic foot. On the contrary to a study which showed that a large number (>50%) of participants were found to have poor knowledge of diabetic foot care [16], but in accordance with another Saudi study which found that (76.6%) of patients had good knowledge of diabetic foot and foot ulcers [17]. Pourkazemi, Aydin et al. reported that only 57 participants (15.2%) had good knowledge, most of them (84.8%) had poor knowledge, and the mean score of patients' knowledge was 8.63 ± 2.65 [18]. Desalu, O O et al. found that (78.4%) of patients with poor practice had poor knowledge of foot care [19]. Findings from UK, Iran, Netherlands, India and USA reported inadequate knowledge of self-foot-care among diabetic patients [20].

Source of information about diabetic foot was doctors and nurses in 13% and social media in 11.9% of our participants. Compared to another Saudi study; (11.1%) of patients have attended a class on diabetic foot care, and 81 (22.0%) received education on diabetic foot care from a doctor and 38 (10.3%) from a nurse [21, 22]. Diabetic persons who had been to the diabetic clinic several times may have gathered information over the course of several years of having diabetes, or they may have spent more time with their doctors and nurses to search for and ask for possible explanations that were probably ignored by diabetic persons

who had diabetes for a shorter period of time. When patients with long-term diabetes develop complications such as diabetic foot, physicians and nurses may have taken more time to care for them, according to a new study. Regardless of the length of diabetes, physicians and nurses must understand the significance of educating diabetic patients and their relatives about diabetic complications, such as diabetic foot [23].

In our study; 62.7% reported that diabetic foot risk may be reduced by controlling blood sugar level, 13% by checking the feet every day and several times, and 9.2% reported wearing shoes and socks on a daily basis. Similar results are found in another study, most of the patients were aware that diabetic feet could be prevented by diet, exercise and regular medication (91.1%) and that diabetic foot needed special care (85.7%) [19].

In our study 65.6%, 66.7%, 48.4%, 82.6% and 62.1% of participants knew that skin infections, foot abscess, bone infections, gangrene, and foot deformity are complications of diabetic foot respectively. This was on the line with a study which reported that 69.2% of patients were aware that diabetics are likely to develop foot ulcers and 62.5% were aware of the risk of reduced blood flow in their feet and 66.1% knew that smoking would compound poor circulation [19].

According to our results; good knowledge of diabetic foot was significantly associated with increasing age and educational level but not with marital status. One study showed that in Saudi Arabia; being married, having a secondary and university level of education, and being a government employee had significantly better knowledge of diabetic foot compared with their counterparts [17]. Another study reported that gender, duration of disease, occupation, place of residence, level of education, having diabetic foot ulcer, history of hospitalization, amputation, and other complications had significant relationship with knowledge [24]. In the study by Muhammad-Lotfi, age, gender, level of education, and duration of diabetes had no significant relationship with knowledge, which is in agreement with our current study [25], and also another study indicated a significant relationship between the level of education and knowledge [26]. In Morocco, educational level and socioeconomic status had an impact on awareness of good foot health and care. Poor knowledge of the degenerative complications of diabetes was associated with age, low educational level and low socioeconomic status [27]. Also, a previous study reported that women and those above the age of 50 were less knowledgeable about foot care, although these associations were not statistically significant. Similarly, in some third world countries due to socio-cultural beliefs women are not allowed to attain higher educational status compared with their male counterparts in the family, eventually resulting in women having less knowledge of diabetic foot care [28].

Conclusion:

Comparing to previous national and international figures, level of knowledge of diabetic foot and related complications is average. Due to the high incidence of diabetes mellitus (DM) in Saudi Arabia, it is vital that the population should have appropriate information and awareness of this illness to enable continued promotion of public health measures and to limit its prevalence. It is also crucial for DM patients to understand the medications and lifestyle

modifications that may enable them to better regulate their glucose levels and postpone the onset of problems. DM pathophysiology, risk factors, management, and consequences must be well-understood by patients, families, nurses, and physicians in order to assist patients reach their desired outcome.

COMPETING INTERESTS DISCLAIMER:

Authors have declared that no competing interests exist. The products used for this research are commonly and predominantly use products in our area of research and country. There is absolutely no conflict of interest between the authors and producers of the products because we do not intend to use these products as an avenue for any litigation but for the advancement of knowledge. Also, the research was not funded by the producing company rather it was funded by personal efforts of the authors.
